

Build 01: Piezo-Crystal Plate Pendulum

Purpose

This is the first build to give students. It is cheap, measurable, and hard to fool if the controls are taken seriously.

The device is a small plate with piezoelectric ports. It drives its own resonant modes, reads ringdown and cross-coupling through the same or co-located ports, logs the state onboard, and hangs as a pendulum so tiny horizontal forces can be measured.

Primary goal:

Map ordinary vibration and acoustic forces, then test whether a sign-reversible coherent state produces a residual pendulum deflection after sham, dummy, phase-flip, and physical-flip controls.

Target Specification

Item	First build target
Plate size	80 x 60 mm to 100 x 100 mm
Plate material	Quartz, alumina, glass-ceramic, sapphire, or insulated aluminum
Plate thickness	1 to 3 mm
Active ports	4 or 8 piezo discs, 20 to 27 mm diameter
Port layout	Symmetric pairs across the intended force axis
Drive range	Start 100 Hz to 40 kHz sweep
Drive voltage	Start below 24 Vpp. Increase only after thermal checks
Power	Onboard battery during force measurements
Readout	Same-port ringdown preferred. Co-located pickup piezos acceptable
Sensors	Temperature, accelerometer, magnetometer, battery voltage, drive monitor
Logger	MicroSD or onboard flash with timestamps
Suspension	1.5 to 2.0 m nonconductive line
Force readout	Camera tracking, laser spot, or optical position sensor

Bill Of Materials

Minimum active plate:

- 1 nonmagnetic plate, 80 x 60 mm to 100 x 100 mm.
- 4 to 8 PZT piezo discs, 20 to 27 mm. Cheap buzzer discs are fine for first read/write tests.
- Thin epoxy or cyanoacrylate for bonding piezos to the plate.
- RP2040, RP2350, Teensy, or ESP32-class microcontroller.
- 4 to 8 drive channels. Low-power first pass: MOSFET half-bridge or small H-bridge per port. Higher-power pass: class-D audio amplifier channels.
- Analog switch or relay network to disconnect the driver during ringdown sensing.
- ADC front end with input protection. Use a high-value divider, series resistance, and clamp diodes or TVS protection.
- MicroSD module or onboard flash.
- IMU/accelerometer, 3-axis magnetometer, and at least one temperature sensor.
- LiPo or Li-ion battery, regulator, fuse, and physical kill switch.
- Nonconductive suspension line, 1.5 to 2.0 m.
- Laser pointer and small mirror, or phone camera with a high-contrast fiducial.
- Shield box or transparent acrylic guard.

Matched dummy:

- Same plate outline and mass.
- Same battery mass and electronics envelope.
- Same external coating, tape, heat path, and handling.

- Broken coherent branch: replace piezos with matched capacitors/resistors, scramble phase, add damping, or run record-shuffled firmware.

Mechanical Build

1. Mark the intended force axis on the plate. For a pendulum run this axis points horizontally toward the measuring screen. For a balance run the same hardware can be placed flat, with the axis vertical.
2. Bond piezos in symmetric pairs. A four-port layout uses two ports on one side of the axis and two on the other. An eight-port layout gives better mode control.
3. Keep the center of mass on the suspension line. Add nonmagnetic trim mass if needed.
4. Route wires tightly against the plate. No dangling loops. During force measurements the plate must run from onboard power and logging.
5. Add a small mirror or optical fiducial near the center of mass. If using a laser mirror, keep it light and centered.
6. Put the battery and logger on the moving test article, not on the bench.
7. Build the dummy with the same outside geometry and mass.

Electronics

Each piezo port should support two modes:

- Drive window: the MCU commands a sine, square, or PWM waveform through a protected driver.
- Read window: the driver disconnects, the piezo sits behind a high impedance, and the ADC records ringdown and cross-coupled response.

Minimum safe same-port circuit:

- driver output through 47 to 220 ohm series resistance,
- analog switch or relay disconnect before ADC read,
- ADC input through 1 Mohm / 100 kohm divider or similar,
- clamp diodes to ADC rails,
- firmware dead time between drive and read windows.

For a first student prototype, co-located transmit/receive pairs are acceptable if the geometry is fixed and documented. Label that as logical self-read. Strict same-port status belongs to reversible drive/sense ports.

Firmware States

Implement fixed, timestamped state blocks:

State	Behavior
OFF	Logger only. No drive.
SHAM	Same average power as active, with incoherent or phase-scrambled drive.
ACTIVE_PLUS	Coherent phase/amplitude pattern with the intended force-axis sign.
ACTIVE_MINUS	Same power and frequency set, reversed phase gradient or zone assignment.
DUMMY	Same schedule on the matched dummy.

A practical ACTIVE_PLUS pattern:

- drive side A at phase 0 degrees,
- drive side B at phase +90 degrees, or with a defined amplitude lead,
- read every port after each drive packet,
- compute ringdown amplitude, phase, Q estimate, and cross-coupling matrix.

ACTIVE_MINUS reverses the phase gradient or swaps the A/B zone labels. The power envelope must remain matched.

Pre-Force Checkout

Do not hang the device for a force claim until it has a self-read receipt.

Required checks:

1. Frequency sweep: identify stable plate modes from 100 Hz to 40 kHz.
2. Coupling matrix: drive each port, read all ports, save amplitude/phase/ringdown features.
3. Repeatability: repeat the same state at least 20 times.
4. Prediction test: use records from cycle t to predict held-out readouts from later cycles. Compare against shuffled records.
5. Sign test: show that `ACTIVE_PLUS` and `ACTIVE_MINUS` produce opposite signed feature contrast along the intended axis.
6. Dummy rejection: dummy logs should not produce the same signed self-read scalar.

Pendulum Measurement

Setup:

- Hang the active plate from a 1.5 to 2.0 m line.
- Put the line on a rigid overhead point.
- Enclose the rig to block air currents.
- Let the system thermally settle before recording.
- Track center-of-mass displacement with a camera, or track reflected laser spot displacement from a small mirror.

Direct camera formula:

$$F_{\text{horizontal}} = m * g * x / L$$

where m is moving test-article mass, L is pendulum length, and x is center-of-mass displacement.

Laser mirror formula:

$$F_{\text{horizontal}} = m * g * s / (2 * D)$$

where s is reflected spot displacement on a screen and D is mirror-to-screen distance. This assumes small angles.

Run sequence:

1. Record OFF for drift.
2. Run SHAM, ACTIVE_PLUS, ACTIVE_PLUS, SHAM in ABBA order.
3. Run SHAM, ACTIVE_MINUS, ACTIVE_MINUS, SHAM.
4. Physically rotate the plate 180 degrees around the vertical suspension axis and repeat.
5. Run the matched dummy with the same schedule.
6. Run heater-only or resistor-only controls at the same average power.

Use stable windows after a preregistered settling interval. Keep the raw video or optical position log.

What Students Should Expect

Expected ordinary signals:

- resonance peaks,
- phase-dependent vibration,
- air motion near the plate,
- pendulum motion that tracks acoustic leakage,
- thermal drift after high-power states,
- static effects after handling.

Useful first result:

- a measured force curve or upper bound,
- a clean map of which artifacts dominate,
- a reproducible self-read scalar if the hardware is good enough.

Candidate residual threshold:

- same sign as the pre-force self-read scalar,
- reversed by **ACTIVE_MINUS**,
- reversed by physical rotation,
- absent or much smaller in dummy and sham,
- not explained by temperature, battery voltage, vibration leakage, magnetometer changes, electrostatics, or operator timing.

Safety

- Start below 24 Vpp and low duty cycle.
- Fuse the battery.
- Keep hands away during high-amplitude sweeps.
- Wear eye protection. PZT ceramic can crack.
- Do not use a power or USB cable during force measurements.
- Let piezos cool. Stop if any port exceeds 60 C.
- Treat a positive-looking result as an artifact until the dummy, flip, sham, and thermal controls are complete.
